

Part 1 - Wired Environment

Part 1 - Wireless Environment

I connect two machines to my house wifi. I expected that the throughputs in the wireless environment should be less than in the wired environment. The result met my expectation. Nevertheless, I didn't expect that the throughput would be significantly reduced. I think my house wifi is slow. In a wired network, there are lesser obstacles because all things are in the cable. While in a wireless network, there are so many obstacles in the transient path. For example, I tested on my roommate's computer and my roommate was playing video games.

Part 3 - Q2 Predictions

Expected latency and throughput: Latency should be the sum of avg link1+ avg link2+ avg link3 = 80.18ms+20.641ms+40.826ms=**141.647ms**. Throughput should be the min throughput of link1 & link2 & link3 which is around **20.686 Mbps** (the average between results of client and server).

Part 3 - Q2 Results

The average RTT from h1 to h4 is **142.130ms**. The measured throughput is **20.468 Mbps**. Pretty close to the predictions.

Part 3 - Q3 Predictions

I predict that the latency for multiple pairs' communication is the same as the single pair's, because latency is the time to transfer a data packet. All pairs use the same link, so the latency of the link is the same. The expected latency for 2 pairs and 3 pairs should be **142.130ms**, the

same as above. The throughput should be divided into each pair. I'm not sure about the algorithm of division, so I simply guess the throughput will be evenly distributed to each pair for the sake of fairness. For 2 pairs, each pair's throughput will be **20.686 Mbps/2 = 10.234 Mbps**. For the 3 pairs, each pair's throughput will be around **20.686 Mbps/3 = 6.895 Mbps**.

Part 3 - Q3 Results

The average RTT for 2 pairs (h1-h4, h7-h9) is **141.983 ms** and **143.015 ms**. The result fits my expectation. The latencies are the same for all pairs.

The throughput for 2 pairs (server-client: h1-h4, h7-h9) are **(13.140Mbps|15.330Mbps)** and **(6.152Mbps|7.177Mbps)**. Nevertheless, there are time differences in the order of starting client connection to the server, since I have to manually run start each client one by one. If I start h9 as the client and then h4, the result is just the opposite (**13.823Mbps for h9, 10.147Mbps for h4**). It seems that the throughput for two pairs is divided into **1.5~2:1**.

The average RTT for 3 pairs (server-client: h8-h10, h1-h4, h7-h9) are **145.168ms, 142.239ms, and 143.305ms**. The result fits my expectation. The latencies are around the same for all pairs. The throughput for 3 pairs (h8-h10, h1-h4, h7-h9) are **(13.544Mbps|14.898Mbps), (3.181Mbps|3.605Mbps), and (3.009Mbps|3.410Mbps)**. I started the h10, h4, and finally h9. It seems that the throughput for three pairs is divided into around **4:1:1**. There should be some errors caused by time differences.

Part 3 - Q4 Predictions

The original latency and throughput between h5 and h6 are 82ms and (29.077|31.984Mbps). The original latency and throughput between h1 and h4 are 141.647ms and (19.340|21.274Mbps).

I guess the latencies remain the same (**h1-h4: 141.647ms, h5-h6: 82ms**) for each pair when they communicate simultaneously. For throughput, the throughput of shared link2 might be evenly divided for two pairs ($48.865\text{Mbps}/2 = 24.43\text{Mbps}$). Thus, the min throughput between h1 and h4 is $\min(20.69\text{Mbps}, 24.43\text{Mbps}, 39.57\text{Mbps}) = \mathbf{20.69\text{Mbps}}$. The min throughput between h5 and h6 is $\min(30.232\text{Mbps}, 24.43\text{Mbps}, 30.62\text{Mbps}) = \mathbf{24.43\text{Mbps}}$.

Part 3 - Q4 Results

The average RTT for h1-h4 and h5-h6 are **142.674ms** and **83.946ms**. The results meet the expectation.

The measured throughputs for h1-h4 and h5-h6 are **(client: 21.539Mbps|server: 19.053Mbps) and (31.751Mbps | 28.864Mbps)**. I checked the bandwidth in lab1_topo.py and found that the bandwidth of shared link 2 is 50Mbps. The throughput of h1-h4 is around 20Mbps, and the

throughput of h5-h6 is around 30 Mbps. Thus, the bandwidth of shared link2 is enough for both pairs. Thus, the throughputs of each pair remind the same (around 20Mbps for h1-h4 and 30Mbps for h5-h6).
